THE PREPARATION OF SOME COMPOUNDS FOR TESTING AS INSECT REPELLENTS

Service Directives CWS-32 and SO-6

Endorsement (1) Dr. Joseph Dec, Technical Aide, Division 9 to Dr. Walter R. Kirner, Chief, Division 9.

Forwarding report and noting:

"Reported herein is the submittal of 651 organic compounds, mixtures and creams for testing as insect repellents. The report includes directions for preparation of these materials, their insect repellency testing data and a discussion of the relationship of chemical structure and physical properties to insect repellent effectiveness.

"Among the promising candidate insect repellents tested after application to skin 0-6133, 0-6154, 0-6168, 0-6216, 0-6230 and 0-6252 have "passed" acute toxicity tests and have been submitted for 90-day subacute toxicity studies. 0-6109, 0-6152, 0-6217, 0-6226, 0-6254 and 0-6263 have "passed" (some with reservations) acute toxicity tests but have not been submitted for 90-day subacute toxicity studies. 0-6210, 0-6316, 0-6319, 0-6358, 0-6397, 0-6484, 0-6498, 0-6500 and 0-6503 have been submitted for acute toxicity tests, still to be completed. Seventy-one other compounds whose average repellency times ranged from 181 to 352 minutes against *Aedes aegypti* were not submitted for acute toxicity tests. Among the compounds tested after impregnation in cloth fourteen were repellent against *A. aegypti* more than ten days.

"When the NDRC, Division 9 program on the preparation of candidate insect repellents was terminated shortly after the end of the war with Japan insect repellency data from the field and further toxicity data were needed to evaluate adequately the promising candidate insect repellents prepared under this contract. Toxicity studies are being made. Additional quantities of some of the promising compounds would have to be prepared for repellency tests in the field and toxicity studies.

"The insect repellency data were obtained by the U. S. Department of Agriculture, Bureau of Entomology and Plant Quarantine,

**SUMMARY**

1. As of October, 1945, 631 compounds, mixtures and creams were submitted as candidate repellents. More than 600 of these were individual compounds. Of this number 109 were repellents; these compounds passed the minimum requirements (180 minutes to the first bite vs. Aedes or 120 minutes vs. Anopheles or 10 days to the first bite vs. Aedes in cloth tests).

2. Our results have led to the conclusion that in selecting a candidate repellent consideration should be given to boiling point and functionality. In general a candidate should have a boiling point in the range of 90-130°/0.5 mm. and should be polyfunctional. In one group, chosen with regard to these criteria, 54% of the candidates submitted were repellent.

3. It would appear that the limiting factor to repellent time is the rate of absorption of the repellent by the skin rather than the volatility or chemical structure of the repellent. Absorption thus seems to set an upper limit of about 400 minutes on repellent time.

**RESTRICTED**

## INTRODUCTION

The work on this project, directed toward the development of a satisfactory mosquito repellent, was begun in June, 1944. The ideal repellent as defined by the Army was to be odorless, or have a mild odor, have no undesirable characteristics on application to the skin, be non-toxic and be repellent to all species of mosquitoes for at least twelve hours. At the time that our work began a large number of individual chemicals and industrial products had been tested for insect repellency at Orlando, Florida. These results were compiled and arranged according to chemical groups and served as a basis for future work. The Army had in current use a repellent, 622, which was effective for about two hours.

The first procedure adopted in the selection of candidate repellents, for lack of a theory relating structure to repellency, was the preparation of homologs and analogs of compounds which had indicated repellent properties. The second procedure was the selection and preparation of compounds for which there were no precedents, this procedure being a random search for suggestions for future work. The results of all cooperating laboratories were made currently available through the medium of a card index distributed by a coordination center. On the basis of accumulated data certain chemical and physical prerequisites of a repellent were developed and were used in the later selection of candidates. A list of proposed candidates was submitted before preparation to the coordination center to avoid duplication in preparation.

Compounds selected as candidates were prepared in amounts of 30 g. each for preliminary tests for irritancy and repellency. Five gram samples were submitted, after October, 1944, to the Pure Food and Drug Administration in Washington for preliminary irritancy tests. Simultaneously 25 g. samples were sent to Dr. Knippling at Orlando, Florida for repellency tests. Compounds which were of interest were requested in amounts of 500 g. for acute toxicity tests and further repellency tests. Those compounds which were relatively non-toxic and still were of interest because of their repellency values were then requested in amounts of 4 l. Three liters was submitted for chronic toxicity tests and one liter for further repellency testing at Florida and overseas.

Since our primary objective was the preparation of large numbers of compounds in an effort to survey rapidly the types of chemical compounds, no attempt was made to characterize completely the compounds prepared or to investigate reactions or products which would have been of interest in a classical approach. The compounds submitted were prepared in a state of purity usually better than 95% and characterized sufficiently to establish their identity. In cases where the product was of continued interest and its identity or purity was in doubt, further work was carried out to fully establish its identity and purity.

Inasmuch as our laboratory was equipped for chemical synthesis, we often cooperated with other investigators by preparing quantities of chemicals for their needs.

An attempt has been made to use the latest Chemical Abstract names in the naming of compounds throughout this report.

## STATUS OF STUDIES

It is the purpose of this section to outline the state of our work at the time of contract termination and to indicate where further work may be desirable. A list has been prepared of all compounds submitted for acute toxicity studies and their status indicated by P = passed, C = caution or NP = not passed. At the time the report was in progress data were not available for all these compounds. A similar list has been prepared of the six compounds prepared in amounts of 4 l. and submitted for chronic toxicity studies; no data have been received for these compounds. All those compounds which seemed to warrant further consideration on the basis of acute toxicity and repellency data have been submitted for chronic toxicity studies. Of those compounds submitted for acute toxicity on which no data are as yet available, the following three compounds would be of particular interest if the toxicity testing data are favorable:

- 6316 1,6-Hexanediol, diacetate (if further tests against Anopheles substantiate the DMP ratio of 2.6)
- 6498 Cyclohexanecarboxylic acid, 1-hydroxy-, 2-butoxyethyl ester
- 6503 Ethanol, 1-phenyl-2-propoxy-

Of the many compounds which were repellent but were not submitted for further testing, the following two are deemed of special interest to be prepared for acute toxicity studies:

- 6526 1,2-Ethanediol, 1-phenyl-, 2-propionate
- 6135 Caprylic anhydride

In connection with this review of the current status of our work, it may be of interest to list the laboratories with which we have co-operated so that a complete file of the data relating to our compounds can eventually be prepared.

Table I

## Groups Receiving Samples Directly

- Dr. Copley, Norwich Pharmacal Co., Norwich, N. Y.  
Dr. Haller, Bur. of Entomology and Plant Quarantine, Beltsville, Md.  
Dr. Knippling, Bur. of Entomology and Plant Quarantine, Orlando, Florida  
Dr. Parker, Rocky Mountain Laboratory, Hamilton, Montana  
Lt. Pijan, Naval Medical Research Institute, Bethesda, Md.  
Dr. Smith, Food and Drug Administration, Washington, D. C.  
Dr. Spruyt, National Academy Research Council, Washington, D. C.  
Dr. Yeager, Committee on Inter American Affairs, Washington, D. C.

Further work on new candidate repellents is indicated from our results, however the scope of such work is too great to be discussed in the present report, and could more profitably be done by the group contemplating a continuation of the program.

RELATIONSHIP OF CHEMICAL STRUCTURE AND PHYSICAL PROPERTIES  
TO INSECT REPELLENCY

Everyone who has participated in the work directed toward the development of a repellent has immediately noticed some apparent correlation between a physical or chemical property and repellency. In general, however, these early relationships did not seem to be adequate; numerous exceptions were rapidly evident, until finally the proposed relationship was abandoned. It has been our experience that the only fertile approach was a statistical one and that certain relationships when applied to the selection of candidate repellents would consistently result in obtaining a higher percentage of repellents, but at no time were the results absolute.

Since our approach will be statistical in discussing the factors which we believe are helpful in choosing a candidate, it will be necessary to consider the source and validity of the repellent data and physical constants upon which we base our conclusions.

The people who have worked with mosquitoes have continually emphasized the variability of the data and the many factors which must be considered in standardizing test conditions. Our own observations concerning the factors affecting repellency data are culled from the many reports that we have received and from the large amount of data on compounds submitted for repellency tests. We would like to record these observations under three groups, factors affecting the mosquito, factors affecting the amount of repellent on the arm, and finally variations in data as we have received it.

In noting the factors affecting the mosquito, we wish merely to list those factors that we have been made aware of by reading various reports. The frequency of testing, the acquired tolerance of the mosquito for the repellent, the age, species and sex of the mosquito; the conditions of light or darkness, temperature and humidity, the apparent seasonal variation, all these and no doubt other factors, influence the results of tests. For example, Delong (Monthly Report No. 9) reports the amazing result that at 37° and 100% relative humidity mosquitoes are not attracted by the human and that attraction depends upon a temperature and humidity differential between the skin and the atmosphere. Again, in support of seasonal variation, we have noticed that during certain months the data received from Orlando have been uniformly low for all cooperating laboratories, while at other times the percentage of repellent compounds is greatly increased.

Of the factors affecting the amount and distribution of the repellent on the arm, the individual variation of the test subject is immediately apparent. The care of application, required to insure an even distribution of repellent, the size of the forearm, the amount of hair present are important variables. The rate of absorption (which varies with the individual, the temperature, which influences the rate of peripheral circulation, and the type of the compound being tested) is perhaps the

most important factor in the breakdown of repellent materials. A study has been made by the British (Sir R. Christophers - British Report) of the relation of surface tension and of viscosity to repellency. Repellency did not seem to vary in any regular fashion with surface tension, but viscosity was directly related. There appeared to be an optimum viscosity which would hold "creep" to a minimum and yet not prevent ready and thorough spreading upon application. "Creep" was responsible for a draining of the repellent with the formation of bare areas and attendant early breakdown. Volatility of the repellent did not appear to be an important factor influencing the amount of repellent except as the odor affected mosquitoes. The testing of candidates under sweating conditions and mechanical removal by contact, clothes or rain also affect the amount and distribution of repellent.

The data as received from Orlando were of three types, results on liquids tested directly on the forearm and expressed in minutes, results on solids and irritant liquids tested on cotton hose worn on the arm (these results expressed in days), and so-called paired tests in which the compound is tested simultaneously with a sample of dimethyl phthalate and the results expressed in minutes reported for both. These last results are often expressed as a "dimethyl phthalate ratio" where the value of dimethyl phthalate forms the denominator. By convention liquid compounds with repellent times of more than 179 minutes against Aedes or 119 minutes against Anopheles are considered repellent while solids or irritant liquids tested on cloth with repellent times of 10 days or more are termed repellent. In general paired tests are conducted only with repellent materials. The value of 10 days adopted for solids is roughly equivalent to the values used for liquids.

A third group of observations which indicate the reliability of the data is the variation in the data as reported. Numerous examples may be cited to show the general consistency of results and the validity of using the data in an analysis. However to indicate the range of variation and to form a foundation to explain some apparently anomalous results, examples will be cited of apparent inconsistencies in data. The first and perhaps a trivial example is the occurrence of errors in arithmetic and transcription. Obvious errors are those where the mean values recorded are outside of the limits of either extreme. It may be well to note at this point that the data as received records the number of trials, the range in values, and the average value. Errors in transcription are sometimes made evident by duplicate reports of data. An example of day to day variability, which could lead to anomalies in analysis is the following:

Orlando Number	Original Results	Resubmitted sample	Paired Tests
6375	Aedes 2(95-135) <u>115</u> Anoph. 2(16-31) <u>24</u>	4, <u>260</u> : 4, <u>40</u>	4, <u>305/275</u> : 4, <u>43/61</u>

The underlined numbers are the average values; the denominator in the case of the paired tests is dimethyl phthalate. An example of variability on cloth, where one might expect some of the variables to be eliminated, is

phenoxycetio acid which in one series of tests averaged more than 20 days and in a second series averaged zero days. An illustration of another type of variability is the following example of a compound, repellent on the arm, but ineffective on cloth - a rather surprising result,

<u>Orlando Number</u>	<u>Skin Value</u>	<u>Cloth Value</u>
6251	8, 218	0 days (5th bite)

It was hoped that the introduction of paired tests would lead to entirely reproducible ratios. Perhaps the choice of dimethyl phthalate as a comparison substance was unfortunate, but the results are no more consistent than others. Here it will be observed that the ratio

<u>Orlando Number</u>	<u>Original Results</u>	<u>Subsequent Tests</u>
5563	Aedes 443/275 = 1.61 Anoph. 198/53 = 3.74	517/389 = 1.33 193/140 = 1.36

when Anopheles are used varies by a factor of 2.7. In cases where a series of compounds are submitted, the recalcitrant member may be readily detected and resubmitted, but where only a few or one member of a group is submitted, its true value may be overlooked.

We have thus considered in three groups some of the factors which influence the validity of repellent data. Of these factors we believe that the phenomenon of absorption of the repellent by the skin is the single factor most responsible for limiting repellent time. The question of volatility arises and its role as a limiting factor. Comparative studies have been made by Sulzberger (NRC - I.C.C.P. No. 113) on the amount of dimethyl phthalate recoverable from the skin and from a piece of cloth exposed to the same conditions of temperature and humidity. The cloth showed only slight loss in a matter of days while the repellent was present to the extent of only 36% after five hours on the skin. Comparable quantities were applied to skin and cloth. A further example in point is the observation that further applications of repellent, at intervals preceding breakdown of repellency, will extend the repellent time considerably. These and similar results have led one investigator (Elishewitz-private communication) to state that all "repellents" were equally good, the question was how to keep them on the skin. This led to the development of creams and films designed to retain the repellent. For example Sulzberger showed that an ointment compounded with dimethyl phthalate retained 90% of its content of repellent in a five hour period under similar conditions to those described above. Although these creams and films materially increased repellent time they were unpleasant to use and therefore not practicable.

The above discussion might logically lead to the question of what kind of compound should be used as a repellent. The first results indicated that not all materials were repellent, in fact on a random basis only 3-10%

of all materials submitted were repellent. From the above remarks one might conclude that a high boiling, poorly absorbed compound of medium viscosity and low water solubility would be the answer. Our results and those of others however establish the fact that only compounds boiling in a rather narrow range can usually be repellent. This is a necessary but not sufficient condition and leads to the question of what structure plays in determining repellency.

At this point it may be well to discuss the validity of the physical data reported which forms the basis for the conclusion that boiling point is an important parameter in determining repellency. In general the values designated in our report as boiling points were those recorded during the distillation, attendant on purification, of materials submitted as repellents. These distillations were carried out in many different types of columns under varied conditions, and the results therefore are not strictly comparable. Generally, however, we believe that the values would be correct to within  $10^{\circ}$  or less which is of sufficient accuracy for our purposes. The ideal set of values would have been the vapor pressures as determined at  $37^{\circ}$ , but this determination was not practicable. We have chosen boiling points at 0.5 mm. wherever possible and corrected others, for purposes of comparison, to that value using the approximate relationship that boiling point decreases  $10^{\circ}$  for each halving of the pressure.

An analysis of all esters submitted up to February, 1945 was made (Appendix). Of all such compounds submitted, 9% were repellent. By limiting the compounds to those having molecular weights of 175-249 the number of repellents rose to 16%, an increase of 75%. Ninety-two percent of all repellent esters fell in this molecular weight range, which is roughly equivalent to a boiling point range of similar extent. Early in the program a statistical analysis of the compounds then tested was prepared by Wadley (Summary Report, 11-20-44) who concluded with the observation, "it is possible that eventually we can define a certain range in the middle of a series, and find that within it we have successful and unsuccessful repellents; outside of the range, only unsuccessful ones." Similarly, a list of compounds submitted as candidate repellents by Orlando (Jones, private communication) was prefaced by the statement, "and boiling points between 200 and  $300^{\circ}$ . Several of our good repellents have ---- boiling points in this range." This necessary condition was thus early recognized by other workers. Experience with data of homologous and analogous series has indicated that the inclusive range for boiling point is  $80-130^{\circ}/0.5$  mm. This, no doubt, could be narrowed for individual series and by more accurate data. To illustrate this conclusion we have included in Table IV a listing of all repellent hydroxy-esters and amide-esters submitted from this laboratory with their boiling points, corrected in some cases, at 0.5 mm. Considering the extensive range of boiling point possible, the specificity is quite striking. Very few repellent compounds lie outside of this range, however the converse is not true. Any compounds which possess boiling points in this range are non-repellent, and this fact gives rise to a consideration of structure. One further point that is of interest is the fact that each type of compound when submitted as a homologous series shows a repellent peak or plateau.

RESTRICTED

These maxima always fall in the boiling point range described above, but, in terms of repellent time, all maxima are approximately equal. One might interpret this result, and justifiably, as indicating that there is an effective upper limit to repellent time, and while many repellents are still to be found none will exceed previous repellents in activity. However, from other fields of application, one is constantly reminded of the unique which disproves the rule, and hence, the statement is merely appended as an observation summarizing current results.

The relationship of chemical structure to repellency is the remaining question. Here the answer is diffuse and complicated by the fact that every group has at least one representative repellent. No single structure or group of structures or any relationship between groups has been shown to be responsible or essential for repellent action. The most successful approach has been to answer the question - what group or groups are most likely to produce repellent activity.

A side issue would be an effective correlation of absorption and chemical structure, but the data available are not conclusive or even suggestive. An interesting experiment which gives some indication of the relative rates of absorption is the recording of repellent time to the fifth and seventh bites. Noticeable differences were observed which could be attributed only to absorption since evaporation was not significant during such a relatively short time interval. Perhaps this method could be extended to obtain data correlating absorption with chemical structure.

A cursory examination of the data arranged according to chemical groups readily makes apparent certain groups which seem more promising. It is obvious from such an examination that hydrocarbons as a group are non-repellent, as are simple monofunctional esters. Similarly it would appear that acids, amides, and glycols among others are promising fields for further effort. An early suggestion was that compounds be prepared which in themselves were non-repellent but would by oxidation or hydrolysis liberate slowly an active compound. Such suggestions led to the preparation and testing of aldehydes, since acids were effective; and acetals of 1,2 and 1,3-glycols, since many such glycols were active. In most cases where activity was observed, the active material was the original substance and had a boiling point in the proper range,

A complete answer to the question at hand would be obtained only by a systematic statistical survey of all compounds submitted and a revision of such a survey at frequent intervals. This was done in the case of esters by Shenk (Appendix), and a summary of his results indicates the value of the method. Having found that 90% of all repellent esters had a molecular weight between 175-249 a comparison was made of repellent and non-repellent esters in this molecular weight range. These esters were compared according to the number of functional groups present, including any cyclic structure as a functional group. It is observed that 87% of all repellent esters possess three or more functional groups, while only 54% of all the esters are trifunctional. Another comparison showed that of the trifunctional esters 26% were repellent. Thus by imposing functionality and molecular weight as parameters for repellency the chances of

obtaining a repellent was increased from 9% to 26%, an increase of 188%. Only 4.7% of the difunctional compounds tried were repellent.

A further comparison of trifunctional esters reveals the striking effect of the hydroxyl group which increases the possibilities of obtaining a repellent to 56%; the procedure extended to hydroxy-esters shows that the cyclo-group is also effective. These last two conclusions are based on a relatively small amount of data and hence the reliability of the percentages is somewhat lower than those first reached. On the basis of these results a number of cyclo-hydroxy-esters of proper boiling point have been submitted, and it is interesting to note that about 52% of these were repellent. Although this figure could obviously still be improved, the figure does represent a considerable increase over the 9% originally obtained for esters as a group.

We believe that this approach will be equally effective when applied to other groups. At this point we come to the conclusion that all the factors are not evident. One explanation to which we may have recourse is to concede powers of discrimination to the mosquito, but of course this does not answer the question.

We conclude therefore that a compound to be repellent must have a boiling point within a specified range and preferably should be polyfunctional. We have also shown that within these limits the process of absorption appears to provide a limit to repellent activity.

During the course of our work we have empirically found several groups of compounds which yielded relatively large numbers of repellents. In addition to the hydroxy-esters, glycol diesters and amide esters were investigated rather extensively. Several of the glycol diesters showed repellency against Anopheles and hence were of interest. As a group however they did not yield a high percentage of successful candidates. On the other hand the preparation of amide-esters resulted in a high percentage of repellent candidates. Of the 76 amide-esters prepared, not including urethanes which are a special case, 42% were repellent. This number does not consider the added limitation of boiling point, a factor which would definitely increase the percentage of repellents. Forty-three percent of all hydroxy esters tested were repellent whereas 52% of all cyclo-hydroxy-esters were successful. Thus the validity of our earlier conclusions becomes apparent.

To further emphasize these results the figures obtained when these rules are ignored are of interest. Of 64 simple esters submitted, which violate the condition of polyfunctionality, only one was repellent, an average of 0.7%. Of the remaining groups that were tried keto-esters were in general not effective, while amine-esters, especially of the glycine type, indicated some promise.

A tabulation of all repellent compounds submitted has been included in Table V. It will be recalled that repellents are all compounds whose average value against Aedes is greater than 179 or whose average value against Anopheles is greater than 119 or whose value on cloth is better

RESTRICTED

than 10 days. Some compounds are included whose later tests indicate that they are not repellents. They are included in order to report "paired-test" data which are available. It will be noticed that the activity shown against Anopheles, and the total amounts submitted are included. The toxicity data refer to acute toxicity tests and are the same as those shown in an earlier table. Paired test data are included as a ratio and the value of the ratio is also given. In some cases paired test data available from different samples are included separately. In the case of cloth tests the value is given in days; small d indicates days. The structures are included to facilitate visual comparison of the data. The values given under repellent time show the number of tests, and the average repellency. The range is included in Table VII.

#### INSECT REPELLENCY TESTING DATA

A listing has been prepared of all compounds submitted for testing from this laboratory. The compounds are subdivided by functional groups the order of the present card index being followed. The compounds are arranged within the groups into classes of similar types in the order of increasing complexity so that rapid comparison may be made of the data. Liquid compounds were tested against Aedes aegypti and Anopheles quadrimaculatus; the data are reported as number of tests, total range and average repellency in minutes. Solids and irritant liquids were tested on cotton hose; the values in days to the first bite are recorded.

All candidates were first submitted to the Pure Food and Drug Administration for preliminary irritancy tests. These tests were conducted on the intact skin of rabbits; readings were taken at intervals up to 24 hours. An arbitrary scheme for evaluation, described in reports from that laboratory, was devised in which 4 points was allotted for edema and 4 points for erythema, giving a possible maximum of 8 points to any one compound. The indices, their corresponding irritation significance, and their use recommendations are listed in the following table:

Table VI  
Evaluation of Irritation Indices

Score	Irritation	Evaluation
0 - 3	Mild	Passed
3 - 6	Moderate	Passed
6 - 7	Severe	Caution
7 - 8	Severe	Not passed

These tests were begun in October, 1944 and all compounds submitted since that time are reported with an irritation index. Some compounds proved irritant to the test individual at Orlando and are indicated by a I in the appropriate column. The index of refraction and boiling point are included as an aid in establishing the identity and purity of the sample. The numbers under "method of preparation" refer to corresponding sections in the experimental part.

The Naval Medical Research Institute has reported the following average repellent times of several of our repellent compounds under sweating conditions (90° F. dry bulb, 80° F. wet bulb). Two tests were run in each case against *Aedes aegypti*.

Table VIII

## Repellents under Sweating Conditions

Orlando Number	Name	Average Repellent Time Sweating	Average Repellent Time Normal
6133	Cyclohexanecarboxylic acid, 1-hydroxy-, cyclopentyl ester	147	288
6154	1,5-Pentanediol, dipropionate	92	257
6168	Succinamic acid, N,N-diethyl-, propyl ester	84	396
6168-a	Succinamic acid, N,N-diethyl-, propyl ester	147	396
6216	Hydrylic acid, (β-phenyl-, ethyl ester	37	352
6216-a	Hydrylic acid, (β-phenyl-, ethyl ester	139	352
6252	Succinamic acid, N,N-dipropyl-, ethyl ester	162	260
6254	1,3-Cyclohexanediol, monopropionate	155	308

## EXPERIMENTAL

The methods are recorded only in outline form; the exact equipment and technique used is omitted. The order of presentation is that occurring in Table VII. When compounds have been prepared by the same general procedure, they have been assigned identical preparation numbers. The equipment used was that ordinarily available in a well-equipped laboratory; the techniques employed were standard methods.

The large scale preparations were in general handled in several portions; the largest containers were a 12-l. flask and a 90-l. battery jar. References have been included with the descriptive material. Physical constants are reported in Table VII, and average yields are indicated in most cases.

1. These compounds were obtained from stock and judged to be sufficiently pure for testing.

2. These hydrocarbons were obtained as by-products in the reaction between benzylmagnesium chloride and formaldehyde (Tiffeneau, Compt. Rendu, 137, 574 (1903); Gilman, J. Am. Chem. Soc., 56, 1127 (1934)). Bibenzyl was subsequently obtained from the Eastman Kodak Company.

3. 1,1-Diphenylethylene was prepared from phenylmagnesium bromide and ethyl acetate as described in "Organic Syntheses", John Wiley and Sons, N. Y. C., (1941), Coll. Vol. I, p. 226.

4. These alkyl hydrogen succinates and glutarates were prepared by heating the anhydride (1 mole) and the appropriate alcohol (1.2 moles) under reflux at a bath temperature 20-30° above the boiling of the alcohol. Heating was continued for twenty to thirty minutes after the refluxing had subsided and the product was then purified by distillation (yield 85-95 percent). A "Glascol" mantle was found to serve as a convenient heating unit, particularly in the large runs in which a 12-l. flask was used. In this case the course of the reaction was followed by placing a thermometer in the reaction mixture which should be occasionally shaken or stirred. It was found that a sufficiently pure product was obtained by merely removing the excess alcohol from the reaction mixture by distillation in vacuo.

5. The half esters of adipic acid were prepared from the diester, the acid, and the requisite alcohol according to the directions of "Organic Syntheses," John Wiley and Sons, N. Y. C., (1943), Coll. Vol. II, p. 276.

6. The alkyl hydrogen phthalates were prepared from the anhydride, the alcohol and pyridine by a modification of the procedure described in "Organic Reactions," Vol. II, 401 (1944) (cf. Goggans and Copenhagen, J. Am. Chem. Soc., 61, 2909 (1939)).

7. These compounds were prepared by adding the acyl chloride dropwise to a mixture of the appropriate hydroxy compound, some inert solvent such as benzene, ether or chloroform and sufficient pyridine to combine with the hydrogen chloride formed in the reaction (Blaise, Bull. Soc. Chim., (4), 15, 668 (1914)). In the case of glycol monoesters about 75 percent of the theoretical quantity of acid halide was used, the yields of monoester were 50-60 percent.

8. *o*-Ethoxybenzoic acid was prepared from the sodium salt of ethyl salicylate and ethyl iodide. The resultant ethyl ethoxybenzoate was saponified, the free acid being liberated by acidification.

9. The  $\alpha$ -hydroxy acids were obtained by adding concentrated hydrochloric acid to a stirred, cooled mixture of ether, sodium cyanide and the requisite carbonyl compound at such a rate that the temperature did not rise above 0-5° C. The ether was removed and the cyanohydrin converted to the acid by heating with concentrated hydrochloric acid (Bucherer, Ber., 27, 1231 (1896)).

10. These amide-acids were prepared in good yield by heating succinic anhydride with the appropriate amine in benzene for four hours. The acids crystallized from a mixture of benzene and medium-boiling petroleum ether, J. Organic Chem., 6, 774 (1941).

11. Glutaric anhydride was prepared from commercial dimethyl glutarate (du Pont); the ester was hydrolyzed by heating with concentrated hydrochloric acid, and the acid was converted to the anhydride by use of acetic anhydride. Twenty-one hundred grams (60% yield) of the anhydride was obtained from 4900 g. of ester (cf. Org. Syn., Coll. Vol. I, 91 (1941)).

12. These anhydrides were prepared from the proper acid and acetic anhydride as described in "Organic Syntheses," John Wiley and Sons, N. Y. C. (1941), Coll. Vol. I, p. 91.

13. These compounds were made by direct esterification using *p*-toluenesulfonic acid (2-4%) as catalyst. The acid (1 mole), carbinol (1.2-3 moles), catalyst and a suitable solvent such as benzene, toluene, petroleum ether or chloroform were heated under reflux. The water produced in the reaction was removed continually as formed by means of a Dean-Stark moisture trap.

14. The acid chloride was added to a mixture of magnesium, ether and the appropriate carbinol (Spasson, "Organic Syntheses," John Wiley and Sons, N. Y. C. (1940), Vol. 20, p. 21).

15. This methyl ester was made by direct esterification using concentrated sulfuric acid as catalyst (Purdie and Marshall, J. Chem. Soc. 59, 476 (1891)).

16. Several esters were prepared by treating an anhydride with the requisite alcohol in benzene. This procedure was necessary to avoid polymerization which occurred when direct esterification employing an acid catalyst was attempted.

17. These compounds were prepared by heating the glycol or amino-alcohol with the appropriate anhydride in toluene solution under reflux for several hours; the reaction was vigorously exothermic at reflux temperature.

18. These compounds were prepared by heating the glycol or aminoalcohol (1 mole) with 99% formic acid (2 moles) for several hours; the product was isolated by distillation. The yields were 50-95%.

19. A solution of the chloroformate and excess carbinol was boiled for several hours.

20. Phenol esters were prepared by adding the calculated amount of anhydride to a cooled, stirred solution of the phenol in aqueous potassium hydroxide (cf. Chattaway, J. Chem. Soc., 1931, 2495).

21. A suspension of the phosgene-pyridine complex in toluene was treated with an equivalent amount of the requisite phenol (Rabjohn, Org. Syn., to be published).

22. These compounds were obtained by transesterification using p-toluenesulfonic acid as the catalyst.

23. The  $\gamma$ -lactone of  $\alpha$ -hydroxy- $\alpha$ -methylglutaric acid was prepared from levulinic acid and hydrogen cyanide by the method of Block Kreckler and Tolliens, Ann., 238, 288 (1887). The propyl ester was prepared by direct esterification as described in Prep. Method 19.

24. This ester was prepared by heating the acid with methanolic hydrogen chloride.

25. These esters were obtained in good yield by treating a chloroform-ether solution of the alkyl hydrogen phthalate with diazomethane.

26. Furfuryl furoate was prepared by adding  $\gamma$ -furaldehyde to a boiling solution of sodium furfuryloxide, furfuryl alcohol and benzene (Neilson, J. Am. Chem. Soc., 66, 1230 (1944)).

27. Vanillie acid was prepared from vanillin through the oxime. The oxime was dehydrated with acetic anhydride and the resulting acetate of vanillonitrile was hydrolyzed (Raiford and Potter, J. Am. Chem. Soc. 55, 1683 (1933)). An attempt to prepare the acid by permanganate oxidation of vanillin was unsuccessful. The acid was esterified directly (Prep. Method 19).

28. These cyclic ketals, acetals and dioxolanones were prepared by heating a mixture of the carbonyl compound, the dihydroxy compound, benzene and a trace of p-toluenesulfonic acid as catalyst. The water produced in the reaction was removed continuously as formed by azeotropic distillation by means of a Dean-Stark moisture trap (Salmi and Pohjohainen, ber., 72, 798 (1939)).

29. Concentrated sulfuric acid was added to a stirred and cooled mixture of the appropriate dihydroxy and carbonyl compounds (Konigsberger, Ber., 56, 2107 (1923)).

30. Sodium salts of the indicated acids were heated under reflux in alcohol solution with chloroacetone or methyl bromoacetate for several hours (Brewer and Zincke, Ber., 13, 635 (1880)). The yield was 50-60 percent.

31. These pyruvates were prepared by direct esterification as in Prep. Method 13 except that no catalyst was used.

32. These beta-ketesters were prepared by transesterification without a catalyst. The ethyl ester (1.5-2.0 moles) was heated with the requisite carbinol (1.0 mole) at 160° until the ethyl alcohol formed in the reaction had been completely removed. The product was then purified by fractional distillation at reduced pressure (Bacon, Am. Chem. J., 33, 79 (1905)).

33. Diethyl alkylidene-bis acetoacetates were prepared by condensing aldehydes with ethyl acetoacetate in the presence of pyridine. The crude bis-esters were then heated under reflux with acetic acid containing catalytic amounts of sulfuric acid. The resulting ethyl 6-alkyl-2-methyl-4-oxo-2-cyclohexene-1-carboxylates were obtained in 40-50 percent overall yields (Horning, Denekas and Field, J. Org. Chem., 9, 547 (1944)).

34. Diethyl diacetosuccinate was obtained by the condensation of sodiacetosuccinic ester by means of iodine (Knorr, Ann., 306, 339 (1899)).

35. Diethyl  $\beta$ -oxopimelate was prepared by the simultaneous hydration and esterification of 2-furancrylic acid with ethanolic Hydrogen chloride (Marckwald, Ber., 20, 2811 (1887)).

36. These compounds were prepared by direct esterification as described in Prep. Method 13 using a large excess of glycol.

37. These ethyl 2-alkyl-3-hydroxybutyrates were prepared by the hydrogenation of the corresponding acetoacetates over Raney nickel in alcohol at 125-150° C. (Adkins, Connor and Cramer, J. Am. Chem. Soc., 52, 5192 (1932)).

38. These  $\beta$ -hydroxyesters were prepared by the method of Reformatsky from the appropriate  $\alpha$ -bromoesters and carbonyl compounds (Shriner, "Organic Reactions," John Wiley and Sons, N. Y. C. (1942), Vol. I, pp. 16, 17). Turnings of a copper-zinc alloy (92% Zn - 8% Cu) were used instead of the more customary forms of zinc.

39. This compound was prepared by heating propionic acid (0.25 mole), styrene oxide (0.30 mole) and benzene under reflux overnight. The unchanged acid was extracted with dilute sodium carbonate solution and the product purified by distillation. Yield 30%. Sapon. Equiv.: Calcd 194, Found 203.

40. These glycol monoesters were prepared in 50-60 percent yields by adding about 75% of the theoretical quantity of anhydride to the glycol in toluene solution and bringing the mixture to a boil.

41. This glycol monoester prepared according to Method 7 was isolated by selective extraction. This procedure was required in order to free the product from diester, always a contaminant; distillation is not applicable because of similar boiling points. The monoester was freed from glycol by washing with a small amount of water and from diester by treating the residue with a large quantity of water, sufficient to dissolve the monoester, and then extracting the diester with ether. The monoester was recovered by saturating the aqueous solution with salt followed by chloroform extraction, yield 46%. Sapon-Equiv: Calc'd. 172; Found, 179, 181.

42. Propionyl chloride (1 mole) was added with stirring to a mixture of glycol (1 mole), pyridine (1.5 moles) and chloroform at 10°. The chloroform and pyridine were removed by distillation in vacuo. The residue was dissolved in chloroform and washed with dilute hydrochloric acid until acid to litmus and then with water until neutral. The chloroform was removed and the residue was extracted four or five times with equal volumes of low-boiling petroleum ether at -60°. Essentially pure monoester was obtained upon distillation of the residue. Selective extractions was necessary to separate the mono- from the diester as they boil at about the same temperature and fractional distillation is not applicable.

43. 1,4-Cyclohexanediol dipropionate was partially hydrolyzed with potassium hydroxide in 50 percent alcohol (37% yield). This procedure is based on that of Aldersley, Burkhardt, Gillam and Hindley, J. Chem. Soc., 1940, 10.

44. The appropriate chlorohydroxyester (prepared by application of Prep. Methods 9 and 13 to chloroacetone) was heated with freshly fused sodium acetate at 190-200°; the product was extracted with ether, washed and distilled. Yield 75 percent (Fournau and Tiffenau, Bull. Soc. Chim., (4), 15, 22(1914)).

45. Commercial borneol (1 mole), ethyl orthoformate (> moles) and a trace of p-toluenesulfonic acid were distilled at atmospheric pressure to yield the theoretical quantity of alcohol. The residue was distilled in vacuo without removal of the catalyst (55% yield).

46. A mixture of the appropriate ethyl orthoester (1 mole), carbinol (6 moles) and a trace of p-toluenesulfonic acid was heated until the theoretical quantity of alcohol had distilled. The residue was fractionally distilled in vacuo without removal of the catalyst. The yield was 60-85 percent.

47. To a solution of benzotrichloride in an equal volume of dry propanol at 100°, a solution of sodium propoxide (10% excess) in about 23 parts of propyl alcohol was added dropwise. The thick paste was diluted with benzene and filtered. The product was purified by distillation; yield 60 percent (cf. Post, "Chemistry of Aliphatic Orthoesters", Reinhold Publishing Co., N. Y. C. (1943), p. 17).

48. This compound was prepared by the action of alcoholic hydrogen chloride on acrolein; 25% yield (Pingert, Org. Syn., to be published).

49. These acetals or ketals were prepared by transacetalization. The acetal or ketal (1 mole), the hydroxy compound (2-3 moles) or carbonyl compound and a trace of p-toluenesulfonic acid were heated until a theoretical quantity of the replaced compound had distilled (80-90% yields).

50. These acetals were prepared by heating a mixture of the carbonyl compound, ethyl orthoformate, absolute alcohol and a trace of p-toluenesulfonic acid under reflux for 3 - 10 minutes and neutralizing the catalyst with calcium carbonate (Fauly, Ann., 383, 230 (1911)). The yields were 50-90 percent.

51. A mixture of styrene oxide (1 mole) and the carbinol (7 - 10 moles) in which a small amount of sodium had been dissolved were heated under reflux overnight. After washing, the product was purified by distillation (yield 60-80 percent) (cf. Emerson, J. Am. Chem. Soc., 67, 516 (1945)).

52. These compounds were prepared by the catalytic hydrogenation of 4-(2-furyl)-3-butene-2-one (Adkins and Burdick, J. Am. Chem. Soc., 56, 438 (1934)).

53. 4-(2-Furyl)-3-butene-2-one was prepared from acetone and 2-furaldehyde by a Claisen type condensation ("Organic Syntheses," John Wiley and Sons, N. Y. C. (1941), Coll. Vol. I, p. 283).

54. This acylein was prepared by adding ethyl caproate to a stirred mixture of powdered sodium and absolute ether at such a rate that the mixture refluxed rapidly. This synthesis is based on the preparation of butyroin as described in "Organic Syntheses," John Wiley and Sons, N. Y. C. (1943), Coll. Vol. II, p. 114. The yield was 50-60 percent.

55. These compounds were prepared by catalytic hydrogenation using Raney nickel at 125° and 1500 lbs. pressure (Adkins, "Reactions of Hydrogen", Wisconsin Press, (1937), p. 50).

56. These  $\alpha,\omega$ -glycols were prepared by hydrogenolysis of the corresponding diesters using copper-chromite catalyst (Adkins and Wojoik, J. Am. Chem. Soc., 55, 4939 (1933)).

57. 3,4-Diethyl-3,4-hexanediol was prepared from diethyl ketone by a bimolecular reduction ("Organic Syntheses," John Wiley and Sons, N. Y. C. (1941), Coll. Vol. I, p. 459).

58. N, N-Diethylbutyramide was prepared by heating methyl butyrate (40 g.) and diethylamine (30 g.) in a bomb at 200-210° for two days (Adkins, J. Am. Chem. Soc., 56, 2419 (1934)).

59. These N-substituted imides were prepared by adding the appropriate amine to a cold benzene solution of phthalic anhydride or succinic anhydride. The benzene was removed and the amide heated to 200° for thirty minutes to effect cyclization. The phthalimide was distilled under reduced pressure (70-75% yields).

60. Cyclohexene was slowly added to a stirred solution of peracetic acid in acetic acid (Scanlan and Swern, J. Am. Chem. Soc., 62, 2305 (1940)). The temperature spontaneously rose to 60° and the reaction mixture was heated for one-half hour more at 85°. After standing for sixty hours at room temperature the solution was warmed to 60-70° for one hour and poured into water. Sodium carbonate was added until the solution was alkaline, and the mixture was extracted with chloroform. After removal of the solvent, the product was distilled. The yield was 23 percent.

61. The ester-acid chloride (1 mole) (see below) was added dropwise over a period of several hours to a well-stirred mixture of the amine (2.2 moles) and approximately two volumes of dry ether at 0°. Ether and benzene were added to the reaction mixture which was then washed with dilute acid, dilute sodium carbonate solution and cold brine. After drying over anhydrous magnesium sulfate and removal of the solvent, the product was distilled. Occasionally the product was contaminated with a small amount of a white solid which came over in the early part of the distillation and appeared to be the amine hydrochloride. This was removed by filtration. The yield was 70 to 85 percent.

Several succinamates were originally prepared by direct esterification of the corresponding succinamic acid (Prep. Method 10); however, the yields were very poor, probably due to alcoholysis of the amide group, and a better method was sought. This consisted in preparing the half-ester of the appropriate acid (Prep. Method 4), converting it to an ester-acid chloride and condensing the acid chloride with an amine. The ester-acid chloride were conveniently prepared by adding phosphorus pentachloride (1.02 moles) with occasional swirling over a period of 10 - 30 minutes to the ester acid (1 mole). This operation was carried out in a hood. The phosphorus oxychloride formed in the reaction was then removed by distillation in vacuo; the bath temperature not being allowed to rise above 80°. The crude acid chloride was used without further purification. In the case of mono-sec-butyl succinate the product decomposed when phosphorus pentachloride was added and thionyl chloride (2 moles) was used instead. The use of thionyl chloride was in general avoided as the final product (amide-ester) occasionally had an objectionable odor, although it possessed the same refractive index as material prepared by use of phosphorus pentachloride.

62. The ester-acid chloride (1 mole) was added dropwise at a rate such that the temperature did not rise above 5° to a well-stirred mixture of the amine (1.2 moles), 20-25 percent potassium hydroxide solution (1 mole) and some ether at 0°. The layers were separated, the aqueous part extracted once with ether and the combined ethereal portions were washed with dilute acid, dilute alkali and cold brine. After drying over anhydrous magnesium sulfate and removal of the solvent, the product was distilled. Yield 60 to 85 percent of theory. As in Prep. Method 61 a white solid occasionally came over in the early part of the distillation.

63. Ethyl hydrogen maleate (geometric configuration not certain) was prepared by the method of Shields (J. Chem. Soc., 59, 740 (1891)). The maleamic acids were then prepared as described in Prep. Method 61. Ethyl hydrogen maleate proved to be very unstable when efforts were made to prepare it according to the directions in Prep. Method 4. When the product obtained by warming maleic anhydride (1 mole) and ethyl alcohol (1 mole) was directly treated with phosphorus pentachloride (1 mole) and the amide prepared immediately according to Prep. Method 61, variable results were obtained. In one case the yield was 70 percent.

64. These compounds were prepared by heating a mixture of potassium succinimide, the proper haloester and butanol (Clemo and Ramage, J. Chem. Soc. 1931, 49). The yield was 69 percent.

65. The  $\gamma$ -lactone of  $\alpha$ -hydroxy- $\beta$ -methylglutaric acid (Prep. Method 23) was converted to the acid chloride with phosphorus pentachloride. The acid chloride was then condensed with the appropriate amine (Prep. Method 61). The yield was 60-70 percent.

66. Molar quantities of primary alkyl amine and  $\beta$ -keto diester were allowed to stand with a small amount of methanol for three days; the aqueous layer was separated and the product distilled. The yields varied from 60 to 80 percent (Sauer and Adkins, J. Am. Chem. Soc., 60, 406 (1938)).

67. These compounds were made from the appropriate amines and chloroformates essentially as described in Prep. Method 62. The yield was 85 percent.

68. The necessary sodium alkoxide in an excess of the alcohol was added gradually to a molar quantity of  $\alpha$ -chloro-N,N-diethylacetamide (see below). In the case of  $\alpha$ -cyclohexoxy-N,N-diethylacetamide dioxane was used as a solvent; the yields were 64-67%. The procedure is based on that of Pratt and Robinson, J. Chem. Soc., 1925, 168.

$\alpha$ -halo-N,N-dialkylacetamides were prepared in 70 to 80 percent yield by adding the amine (1 mole) slowly to a well-stirred solution of the haloacid halide (1 mole) in absolute ether at -20 to -10°.

69. Diketene was added to the indicated amine in aqueous solution or suspension at 0 - 20° (30-90% yields) (Boese, Ind. Eng. Chem., 32, 16 (1940)). Diketene was prepared by passing acetone over a hot filament (Hurd, "Organic Syntheses," John Wiley and Sons, N. Y. C. (1941), Vol. 21, p. 64) and allowing the ketene to dimerize.

70. Levulinyl chloride was prepared in 55 percent yield by the action of thionyl chloride on the acid in chloroform at 0° (Clemo and Ramage, J. Chem. Soc., 1931, 54). The amides were prepared from the acid chloride and excess amine as in Prep. Method 61.

71. N,N-Dipropyllevulinamide (Prep. Method 70) was reduced with aluminum isopropoxide in isopropanol by standard procedures (35 percent yield) (Mills, "Organic Reactions," John Wiley and Sons, N.Y.C. (1944), Vol. 2, p. 203).

72. These  $\beta$ -hydroxyamides were prepared in 34 to 62% yields from the appropriate carbonyl compounds and  $\alpha$ -halo-N,N-dialkylacetamides (Prep. Method 68) by standard Reformatsky procedures (Prep. Method 38). As was expected the bromoamides gave more satisfactory results than the corresponding chloroamides. Because the use of bromoamides in the Reformatsky type reaction is not mentioned in the latest review which has come to our attention (Shriner, "Organic Reactions," Vol. I, p. 17, John Wiley and Sons, N. Y. C. (1942)) the following hydroxyamides were redistilled and submitted for analysis (Miss E. Herble, this laboratory):

Valeramide,  $\beta$ -hydroxy- $\beta$ -methyl-N,N-dipropyl-

Calo'd for  $C_{12}H_{25}NO_2$ : C, 66.98; H, 11.6  
 Found: C, 66.26; H, 11.4  
           66.17 .. 11.5

Caproamide, N,N-diethyl- $\beta$ -hydroxy- $\beta$ -methyl-

Calo'd for  $C_{11}H_{23}NC_2$ : C, 65.67; H, 11.4  
 Found: C, 64.91; H, 10.9  
           64.81      11.0

Cyclohexaneacetamide, N,N-diethyl-1-hydroxy-

Calo'd for  $C_{12}H_{25}NO_2$ : C, 67.57; H, 10.37; N, 6.57  
 Found: C, 66.84; H, 10.40; N, 6.53  
           66.94      10.55      6.60

Cyclohexaneacetamide, 1-hydroxy-N,N-diisopropyl-

Calo'd for  $C_{14}H_{27}NO_2$ : C, 69.71; H, 11.2  
 Found: C, 69.48; H, 10.8  
           69.43      10.8

Hydrazylamide, N,N-diethyl- $\beta$ -phenyl-

Calo'd for  $C_{14}H_{19}NO_2$ : C, 70.59; H, 8.60  
 Found: C, 69.29; H, 8.16  
           69.35      7.73

73. These N,N-disubstituted glycine esters were prepared by adding the requisite bromoester to two moles of the secondary amine at 0° (80% yields) (V. Braun, Ber., 40, 3941 (1907)).

74. This group of substituted glycine esters was prepared by adding the indicated primary amine to one mole of the necessary bromoester at 0° (Alpern and Weizmann, J. Chem. Soc., 1911, 86). The yields were 30-40 percent.

75. The appropriate hydroxyamine was refluxed with sodium chloroacetate in aqueous solution for seven hours. After removal of the water by distillation in vacuo the residue was distilled (60% yield) (Chem. Abs., 34, 1023 (1940)).

76. These aminosteres were prepared by treating the potassium derivatives of pyrrole with the proper bromoester as described by Sohl and Shriner (J. Am. Chem. Soc., 53, 4168 (1931)). The yields were 25-45%.

77. Phenylethylene oxide was heated under reflux with a slight excess of the appropriate amine (Emerson, J. Am. Chem. Soc., 67, 516 (1945)).

78. This oxime (Kling, Ann. Chim. Phys., (8), 5, 481 (1905)) was prepared in 80 percent yield from acetal acetate by the method of Huckel and Loehs (Ann., 498, 162 (1932)). The product was extracted with ether and distilled.

79. Benzenesulfonyl chloride was treated with methanol and alkali according to standard procedure; the yield was about 50 percent.

80. Tetramethyl tetrathioorthoformate was prepared from S-methylisothiourea sulfate according to the directions of Baeker and Stedhouder (Rec. Trav. Chim., 52, 926 (1933)).

81. This orthocarbonate was made by the action of chloropicrin on sodium 2-methoxyethoxide (38% yield) (Hartel, Ber., 60, 1841 (1927)).

## APPENDIX

Prepared by W. J. Shenk, Jr.

A statistical analysis by functional groups of all the compounds in our card index as of February 15, 1945, which have average repellency times of better than 180 minutes (or ten days in the case of cloth test) to the first bite against *Aedes aegypti* or 120 minutes against *Anopholes quadrimaculatus* has been made. The compounds which meet the above requirements are hereinafter referred to simply as repellent compounds, all others being classed as non-repellent. All of the esters of Group IV of the classification system were similarly analyzed.

The analyses have the weaknesses of statistical analyses in general but we believe that when completed they will give an illuminating survey of the types of compounds tried and not tried and of the chances of obtaining a repellent by making a certain type of compound.

Analysis of Repellent Compounds:

The repellent compounds were extracted from our card index of the testing results obtained at Orlando. As in the card index, the compounds were separated according to molecular structure into the ten chief groups listed in the left hand column of Table IX. It is important to note that in classifying poly functional compounds the following order of group preference was arbitrarily assigned: X, VIII, IX, I, II, III, IV, V, VI, VII. Thus an amide-ester is in group VIII-a and not group IV. The compounds in each chief group were then analyzed for the following functional groups; cyclo (any cyclic structure), hydroxyl, ether, ester and ketone. The results of the above analysis are summarized in Table IX.

The first column of figures in Table IX gives the number of repellent compounds in the chief groups; the total number is 227. The columns of figures under the headings cyclo, hydroxyl, ether, ester and ketone give the number of compounds in the chief group which contain one or more of the indicated functional groups. It is to be noted that when the column heading is the same functional group as that of the chief group, the figure given indicates the number of compounds containing two or more of such groups. Thus, if Group V (ethers) is under consideration, the figures reading from left to right denote that of the 44 repellent ethers 37 contain one or more cyclo groups, 30 one or more hydroxyl groups, 17 two or more ether groups and 6 one or more ketone groups. The blank in the ester column arises from the fact that ether-esters are classified in Group IV (esters) in accordance with the order of preference rule.

The columns are then summed up, but in order to obtain the total number of compounds containing one or more functional groups of a given kind, the number of compounds in the chief functional groups which were not included in the column must be added. Thus to obtain the total number of repellent compounds which contain one or more ether groups, 27 must be added to the total of 63 at the bottom of the ether column, because only 17 of the 44 Group V ethers are represented in this column.

## RESTRICTED

Percentage of 227	75%	41%	40%	41%	63	72%	47	76 21%

RESTRICTED

Under the heading of Number of Groups Present, the number of compounds in each chief group having a total irrespective of kind of one, two, or three or more functional groups is tabulated. In the three or more classification the great majority have three functional groups. The last two columns record the average molecular weight and the molecular weight range of each of the chief groups respectively. It is to be noted that the molecular weight range is considerably shortened when the middle ninety percent of the compounds in a chief group are considered. Thus, the range of Group IV is shortened from 145-284 to 175-245.

In the last row the fractions of the 227 repellent compounds having the indicated properties are listed in percents. However, in order to evaluate these findings it is necessary to make a comparison between the repellent and the corresponding non-repellent compounds, that is to say to determine what percentage of the non-repellent compounds have cyclo groups etc. As a start such a comparison was made in the case of Group IV esters.

#### Analysis of Group IV:

A total of 763 Group IV esters have been tested; of these, 70 or 9.2 percent are repellent.

Of the 70 repellent esters 64 or 92 percent fall in the molecular weight range 175-249, whereas only 399 or 52 percent of all esters tried fall in this range.

Or looking at it another way, of the 399 esters in the molecular weight range 175-249, 64 or 16 percent are repellent. Thus by limiting molecular weight to a range of 175-249 the chances of making a repellent ester will be increased from 9.2 to 16 percent or by 75 percent. Therefore, molecular weight<sup>+</sup> is important.

#### Group IV Esters in the Molecular Weight Range 175-249

A comparison between repellent and non-repellent esters with molecular weights in the range 175-249 is presented in Table X. The first column of figures gives the number of repellent and non-repellent esters in Group IV which fall in the molecular weight range of 175-249 and finally at the bottom the percentage of the total number tested which are repellent. The next seven columns tabulate the numbers and percentages of the repellent and non-repellent compounds which contain one or more of the indicated groups with the exception of the ester column which denotes diesters. The last three columns give the numbers of repellent and non-repellent compounds which contain one, two, or three or more functional groups.

---

<sup>+</sup>Actually we believe that the vapor pressure of the compound at 37° C. is the important factor and have merely used molecular weight by way of a crude approximation of vapor pressure.

Table I  
Comparison of Repellent and Non-repellent Group IV Esters having molecular weights  
in the Range 175-249

	No. of Functional Groups										
	Number Present	Cyclo	Non-Cyclo	Hydroxy	Phenolic	Ether	Ester	Keto	I	II	III
Repellent	64	54	10	25	0	21	10	3	1	7	56
Percent of Total Repellent	38.4	16	39	6	33	16	47	1.6	11	87.4	
Non-Repellent	335	387	246	33	18	74	114	28	142	160

RESTRICTED

By comparing the various percentages in the bottom row with the 16 percent average value, it can be seen that the presence of cyclo, hydroxyl, and ether groups enhances the chances that a Group IV ester candidate will be repellent. It can be further seen that the presence of a second ester group halves the chances of obtaining a repellent. Of particular significance is the fact that 56 or 87.4 percent of the repellent esters in Group IV which fall in the molecular weight range 175-249 possess three or more functional groups, whereas only 216 or 54 percent of all esters in this category have this number. Also of the 216 esters containing three or more groups 56 or 26 percent are repellent. Thus by choosing only esters which have molecular weights in the range 175-249 and possess three or more functional groups, the chances that a candidate ester will be repellent have increased from 9.2 to 26 percent, an increase of 138 percent. The importance of the presence of three or more functional groups is further emphasized by the fact that only 4.7 percent of the difunctional compounds tried were repellent.

Group IV Esters in the Molecular Weight Range 175-249  
and Possessing Three or More Functional Groups:

A comparison between the repellent and the non-repellent esters which have molecular weights in the range 175-249 and contain three or more functional groups is presented in Table XI. This table was compiled in fashion similar to that described for Table X.

By comparing the various percentages in the bottom row with the 26 percent average for all compounds in this category the striking effect of the presence of a hydroxyl can be seen, for it has increased the chance that a candidate will be a repellent from 26 to 56 percent or by 115 percent. However, enough compounds of this type have not been tried to make the result statistically significant.

Because of the unusual showing of the hydroxyl group in Table XI a comparison between repellent and non-repellent hydroxy-esters in the molecular weight range 175-249 was made and is presented in Table XII. This table was again compiled in fashion similar to that described for Table X.

In Table XII it is noted that the hydroxyl group has a marked effect on repellency, particularly in cyclic compounds; however, in conjunction with an ester group alone it is insufficient.

In general it is concluded that in selecting a candidate ester, the ester should have a molecular weight between 175-249 (preferably a boiling point between 80 and 120° C. at 0.5 mm.) and that it should contain three or more functional groups. Of these groups the hydroxyl, cyclo, and ether groups, in that order, are noticeably beneficial whereas the presence of a second ester group is definitely detrimental. Enough keto-esters have not been prepared to warrant any conclusions with regard to them. Again it is to be emphasized that these conclusions are the

ABSTRACT:

EO 1C501 dd 5 NOV 1953

This report contains the performance results of 631 organic compounds, mixtures and creams which were tested as insect repellents. Among the promising insect repellents tested after application to skin, 0-6133, 0-6154, 0-6168, 0-6216, 0-6290, and 0-6252 have passed acute toxicity tests and have been submitted for 90 day subacute toxicity studies. 0-6109, 0-6152, 0-6217, 0-6226, 0-6254 and 0-6263 have passed acute toxicity tests with some reservation and were not submitted to subacute toxicity studies. Results have led to the conclusion that in selecting a candidate repellent consideration should be given to boiling point and functionality. In general a candidate should have a boiling point in the range of 90-130°/0.5 mm and should be polyfunctional. 54% of the candidates submitted with regard to these criteria were repellent.
